What are the Effects of Earthquakes? - USGS

Rather it is how earthquake ground motions affect structures, their contents, and the soils they are built on, that drive the risk. To understand our risk of losses from earthquakes we must understand the ground motion hazard at a given site as well as how vulnerable or fragile our structures and infrastructure are to these ground motions.

Ground Motion | Pacific Northwest Seismic Network

Strong ground motion during an earthquake can cause water-saturated, unconsolidated soil to act more like a dense fluid than a solid; this process is called liquefaction. Liquefaction occurs when a material of solid consistency is transformed, with increased water pressure, in to a liquefied state.

magnitude subduction" earthquakes to refer to events like the 2010 Chile and 2011 Tohoku earthquakes. 2. DEVELOPMENT OF PRELIMINARY LONG DURATION GROUND MOTION SETS To determine the effect of strong motion duration on structural response, ground motion sets of varying durations are used in this study through nonlinear time history analyses.

Preliminary Assessment of Ground Motion Duration Effects ...

The basic physics of earthquakes is such that strong ground motion cannot be expected from an earthquake unless the earthquake itself is very close or has grown to be very large. We use simple seismological relationships to calculate the minimum time that must elapse before such ground motion can be expected at a distance from the earthquake, assuming that the earthquake magnitude is not ...

1. Introduction. Earthquake-induced landslide hazard is commonly quantified by the accumulated seismic displacement of slopes (D) during an earthquake shaking.Probabilistic seismic displacement analysis accounts for all earthquake and ground motion scenarios and variability associated with the earthquake scenarios, the ground shaking level and the seismic displacement hazard of slopes, and ...

The term "basin effects" refers to entrapment and reverberation of earthquake waves in soft sedimentary deposits underlain by concave basement rock structures. Basin effects can significantly affect the amplitude, frequency, and duration of strong ground motion, while the cone-like geometry of the basin edges gives rise to large amplitude surface waves through seismic wave diffraction and energy focusing, a well-known characteristic of basin effects.

Modification of the input bedrock ground motion by the overlying unconsolidated materials. Amplification causes the amplitude of the surface ground motion to be increased in some range of frequencies and decreased in others.

Procedures for Estimating Earthquake Ground Motions

An earthquake (also known as a quake, tremor or temblor) is the shaking of the surface of the Earth resulting from a sudden release of energy in the Earth's lithosphere that creates seismic waves.Earthquakes can range in size from those that are so weak that they cannot be felt to those violent enough to propel objects and people into the air, and wreak destruction across entire cities.

For sure, one of the most dangerous effects of an earthquake is a Tsunami. Tsunamis are giant waves that can cause floods and in some cases may reach up to 100 feet in height. These deadly waves strike a great distance from the epicentre.
